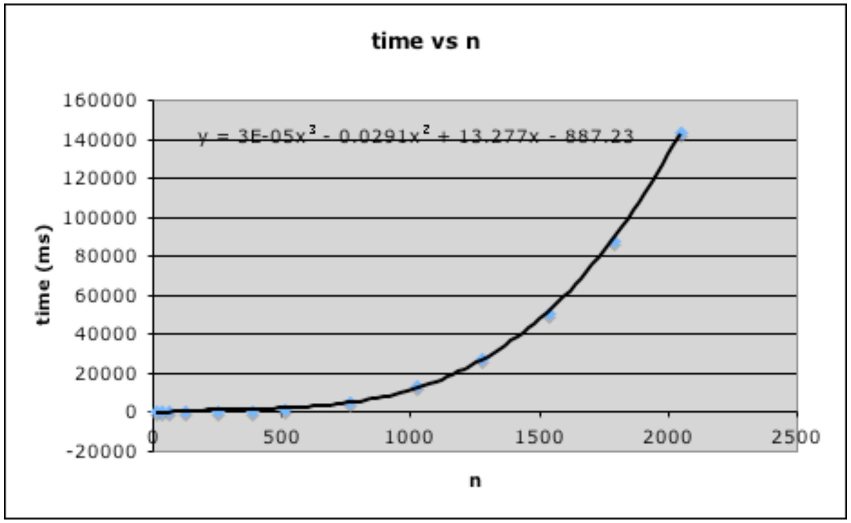
# Divide and Conquer

Summer 2011

Larry Ruzzo

Thanks to Paul Beame, James Lee, Kevin Wayne for some slides

# hw2 – empirical run times

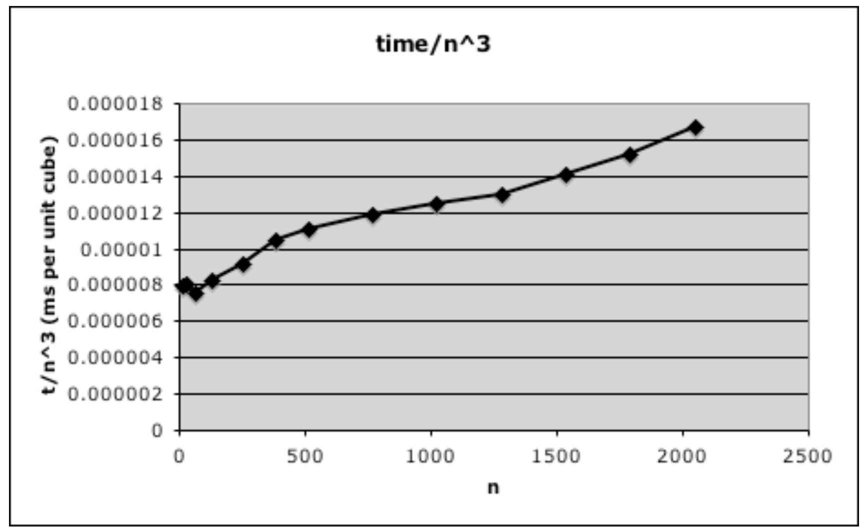


Plot Time vs n

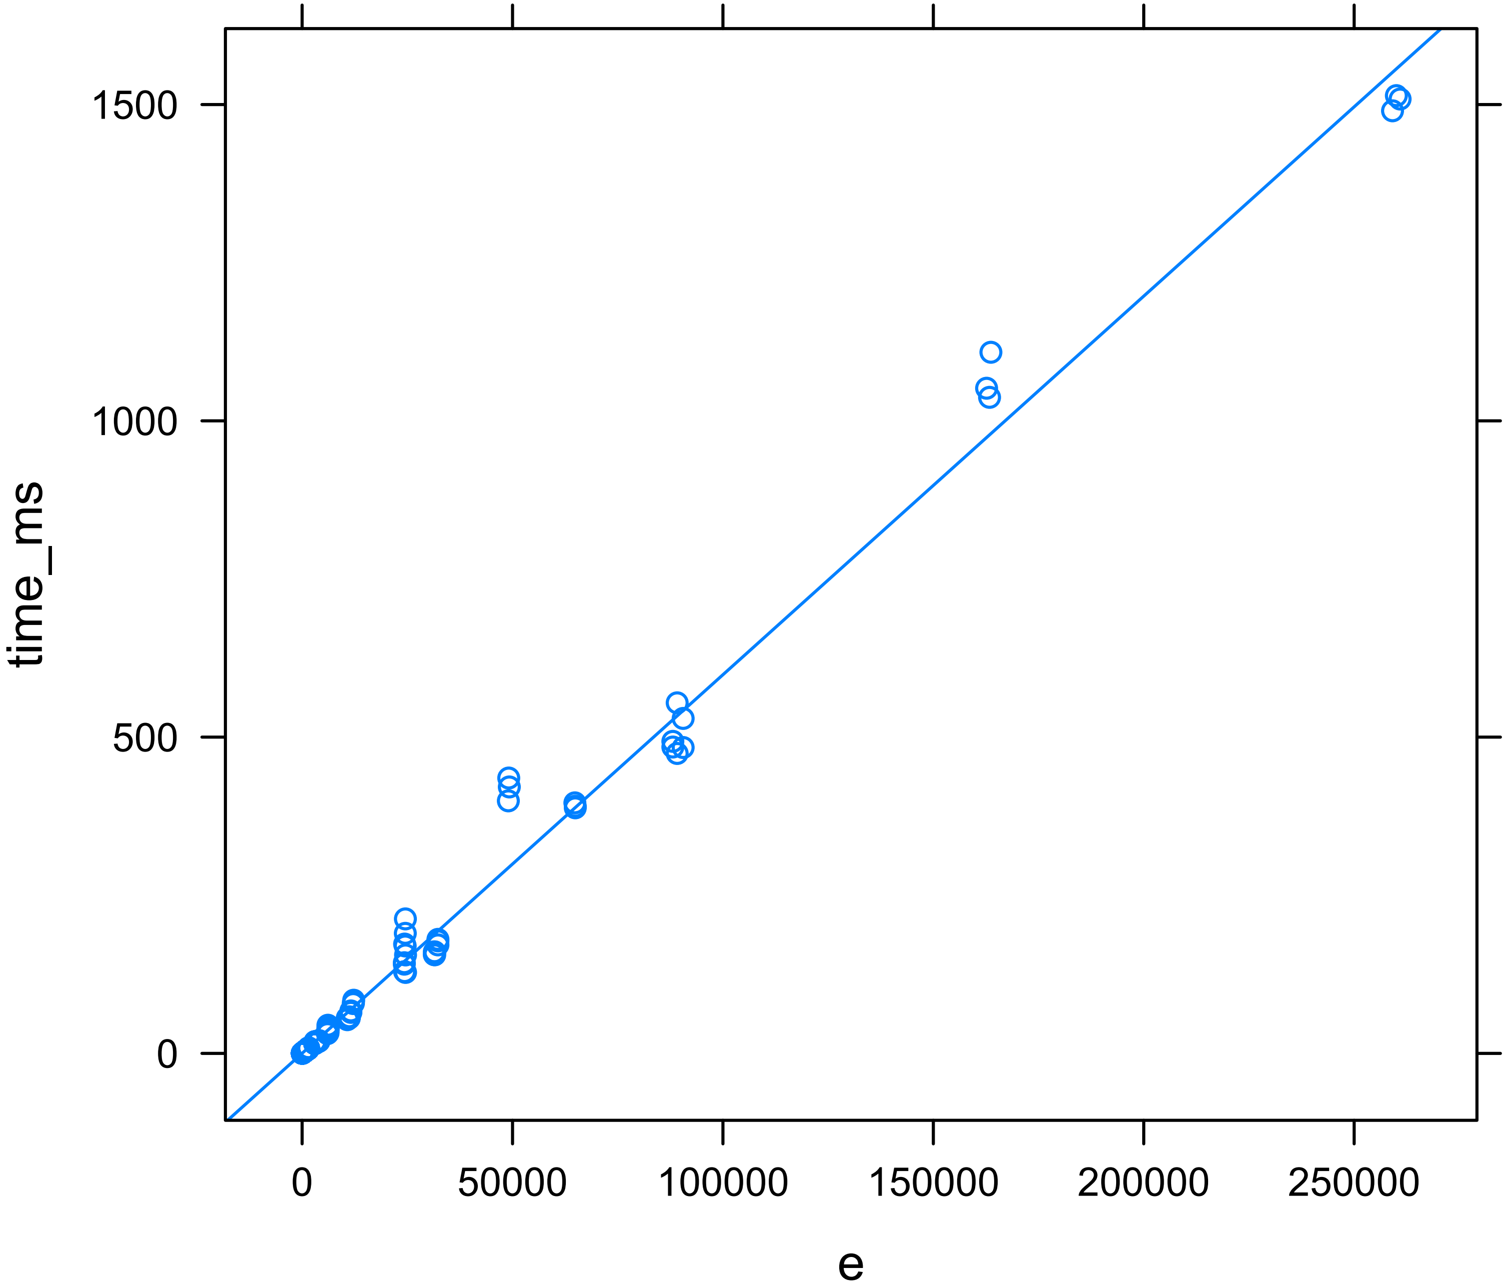
Fit curve to it (e.g., with Excel)

Note: Higher degree polynomials fit better…

Plotting Time/(growth rate) vs n may be more sensitive – should be flat, but small n may be unrepresentative of asymptotics



# biconnected components: time vs #edges



# Outline:

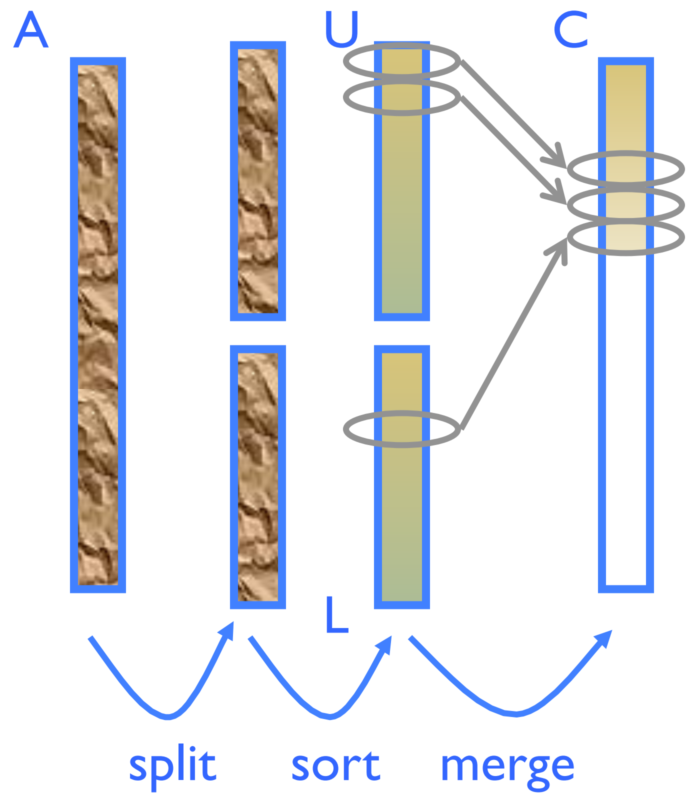
- General Idea
- Review of Merge Sort
- Why does it work?
  - Importance of balance
  - Importance of super-linear growth
- Some interesting applications
  - Closest points
  - Integer Multiplication
- Finding & Solving Recurrences

# Divide & Conquer

- Reduce problem to one or more sub-problems of the same type
- Typically, each sub-problem is at most a constant fraction of the size of the original problem
- Subproblems typically disjoint
- Often gives significant, usually polynomial, speedup
- Examples:
  - Mergesort, Binary Search, Strassen’s Algorithm, Quicksort (roughly)

```
MS(A: array[1..n]) returns array[1..n] {
    If(n=1) return A;
    New U:array[1:n/2] = MS(A[1..n/2]);
    New L:array[1:n/2] = MS(A[n/2+1..n]);
    Return(Merge(U,L));
    }

Merge(U,L: array[1..n]) {
    New C: array[1..2n];
    a=1; b=1;
    For i = 1 to 2n
        C[i] = "smaller of U[a], L[b] and correspondingly a++ or b++";
    Return C;
    }
```



Alternative "divide & conquer" algorithm:

Sort n-1

Sort last 1

Merge them

$T(n) = T(n-1)+T(1)+3n \quad \text{for } n \geq 2$

$T(1) = 0$

Solution: $3n + 3(n-1) + 3(n-2) \ldots = \Theta(n^2)$

Suppose we've already invented DumbSort, taking time $n^2$

Try *Just One Level* of divide & conquer:

DumbSort(first n/2 elements)

DumbSort(last n/2 elements)

Merge results

Time: $\boxed{2\,(n/2)^2 + n = n^2/2 + n \ll n^2}$

D&C in a nutshell

*Almost twice as fast!*

## Moral 1: “two halves are better than a whole”

Two problems of half size are *better* than one full-size problem, even given O(n) overhead of recombining, since the base algorithm has *super-linear* complexity.

## Moral 2: “If a little's good, then more's better”

Two levels of D&C would be almost 4 times faster, 3 levels almost 8, etc., even though overhead is growing. Best is usually full recursion down to some small constant size (balancing "work" vs "overhead").

In the limit: you’ve just rediscovered mergesort!

# Moral 3: unbalanced division less good:

$$(.1n)^2 + (.9n)^2 + n = .82n^2 + n$$

The 18% savings compounds significantly if you carry recursion to more levels, actually giving O(nlogn), but with a bigger constant. So worth doing if you can't get 50-50 split, but balanced is better if you can.

This is intuitively why Quicksort with random splitter is good – badly unbalanced splits are rare, and not instantly fatal.

$$(1)^2 + (n-1)^2 + n = n^2 - 2n + 2 + n$$

Little improvement here.

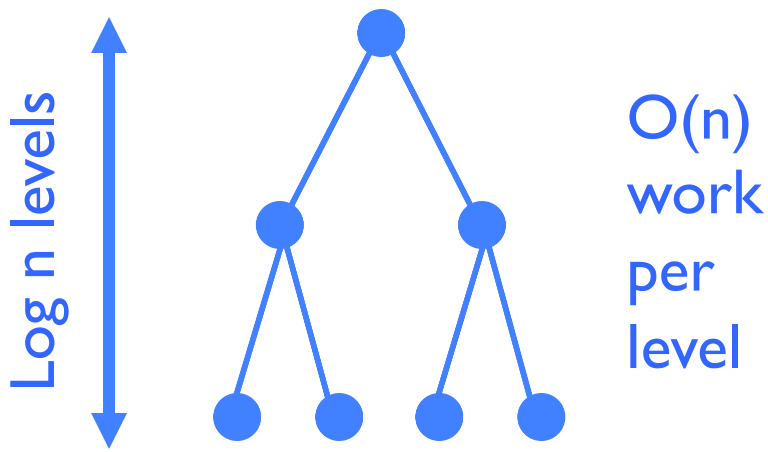
Mergesort: (recursively) sort 2 half-lists, then merge results.

$T(n) = 2T(n/2)+cn, \quad n \geq 2$

$T(1) = 0$

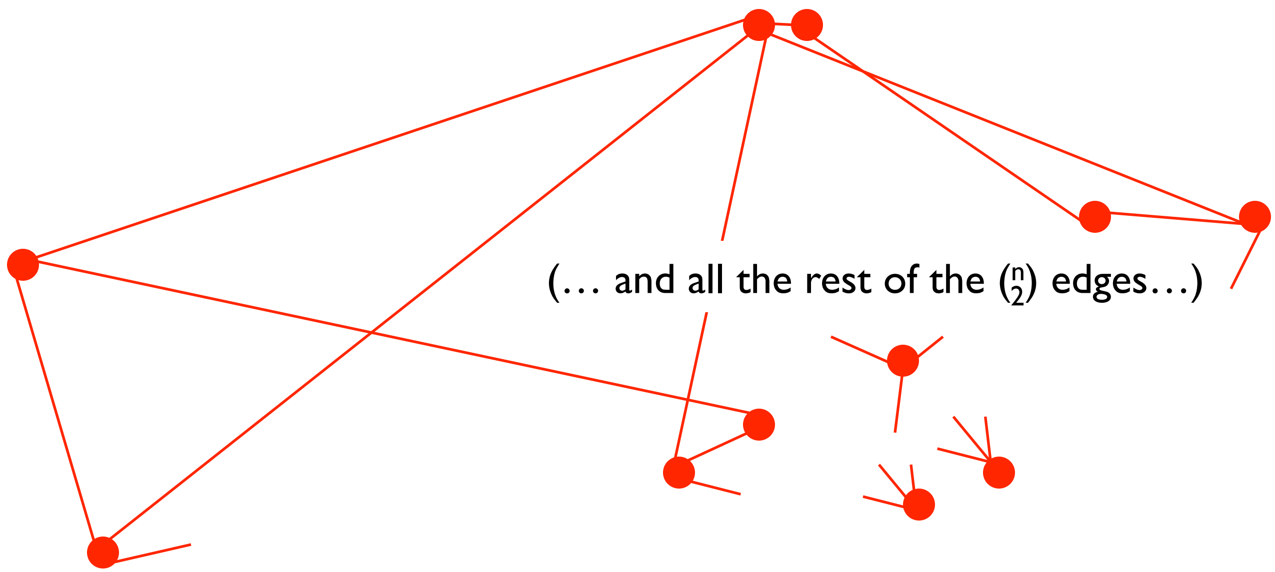
Solution: $\Theta(n \log n)$

(details later)



# A Divide & Conquer Example: Closest Pair of Points

Given n points and *arbitrary* distances between them, find the closest pair. (E.g., think of distance as airfare – definitely not Euclidean distance!)

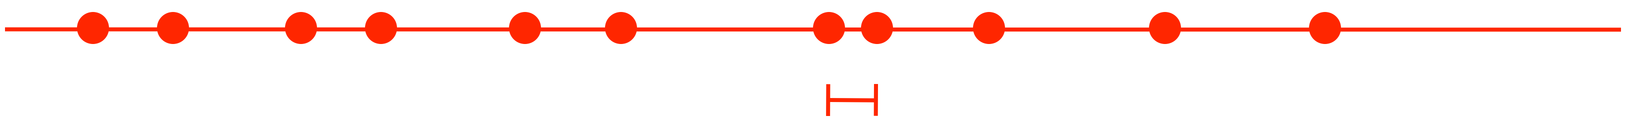


*Must* look at all n choose 2 pairwise distances, else any one you didn't check might be the shortest.

Also true for Euclidean distance in 1-2 dimensions?

## closest pair of points: 1 dimensional version

Given n points on the real line, find the closest pair



Closest pair is *adjacent* in ordered list

Time O(n log n) to sort, if needed

Plus O(n) to scan adjacent pairs

Key point: do *not* need to calc distances between all pairs: exploit geometry + ordering

# closest pair of points: 2 dimensional version

Closest pair. Given n points in the plane, find a pair with smallest Euclidean distance between them.

Fundamental geometric primitive.

- Graphics, computer vision, geographic information systems, molecular modeling, air traffic control.
- Special case of nearest neighbor, Euclidean MST, Voronoi.

fast closest pair inspired fast algorithms for these problems

Brute force. Check all pairs of points p and q with $\Theta(n^2)$ comparisons.

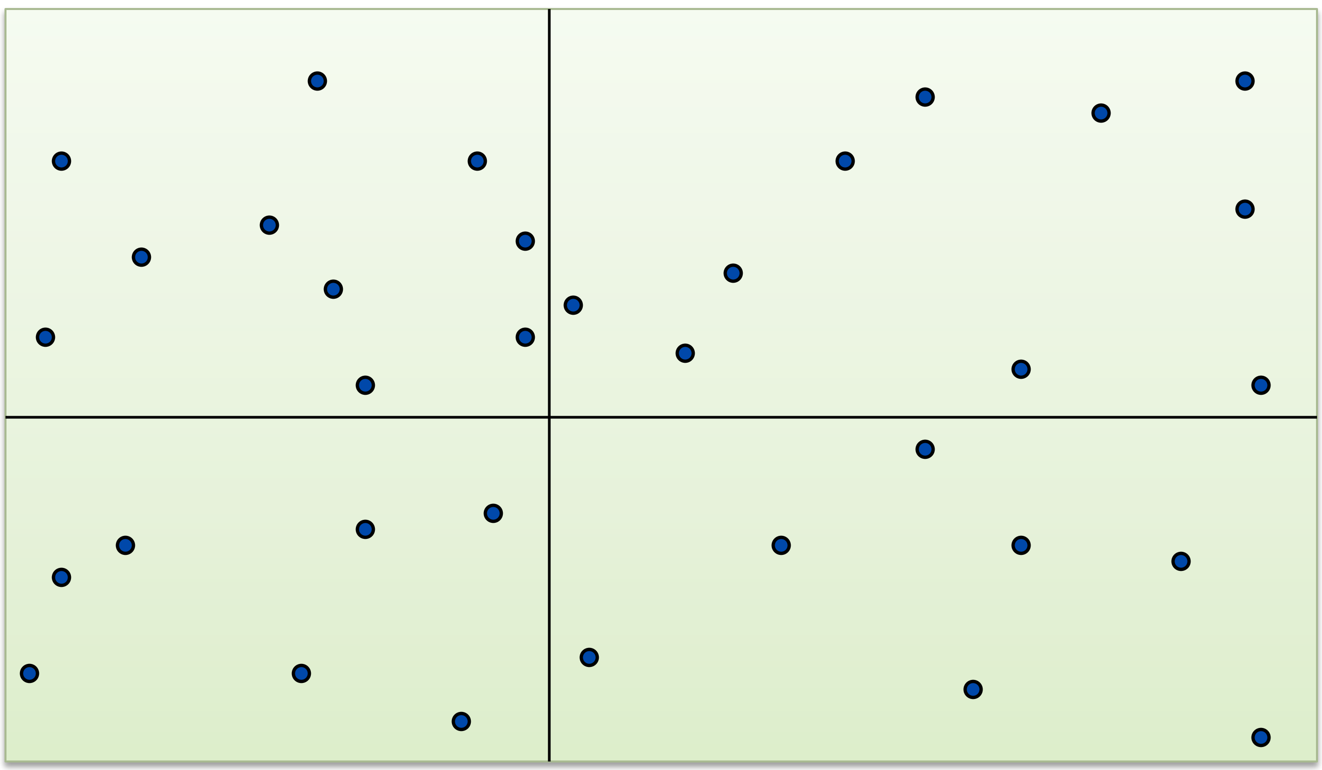
1-D version. O(n log n) easy if points are on a line.

Assumption. No two points have same x coordinate.

Just to simplify presentation

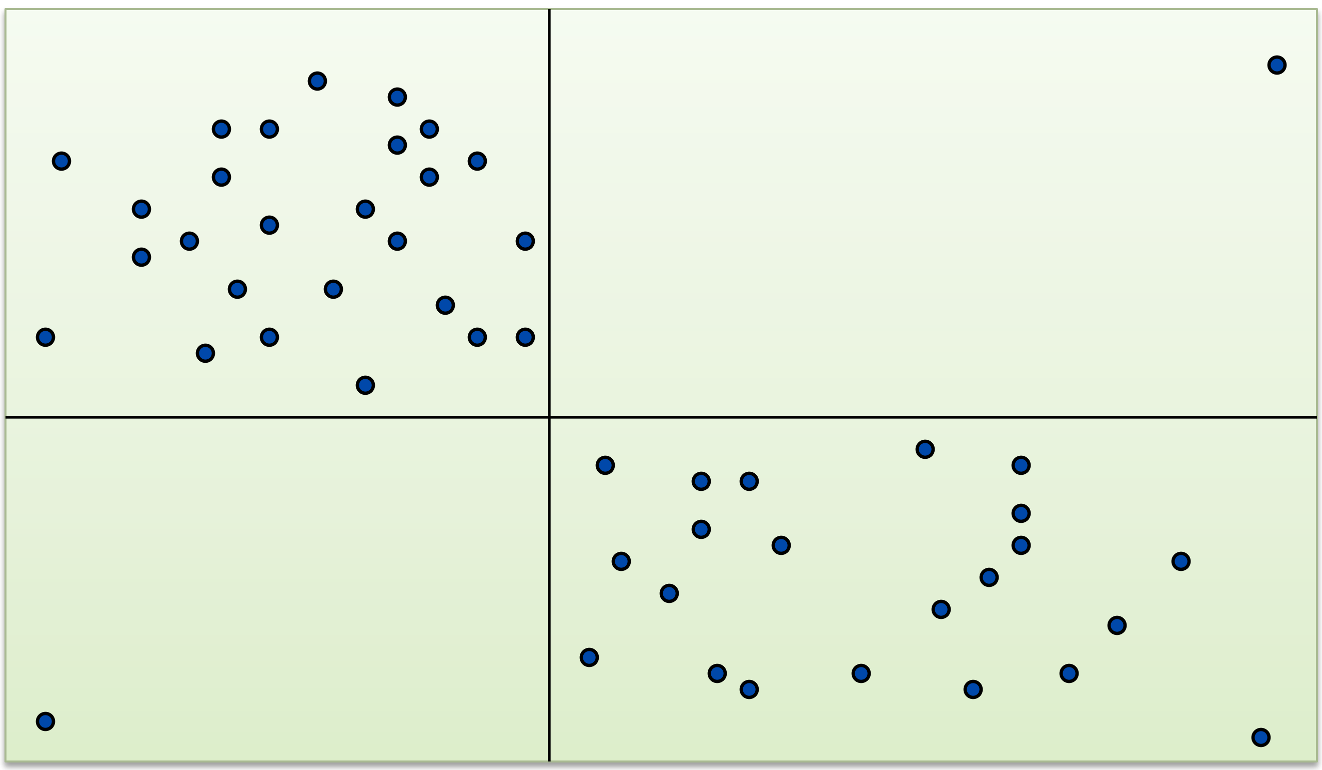
# closest pair of points. 2d, Euclidean distance: 1st try

Divide. Sub-divide region into 4 quadrants.



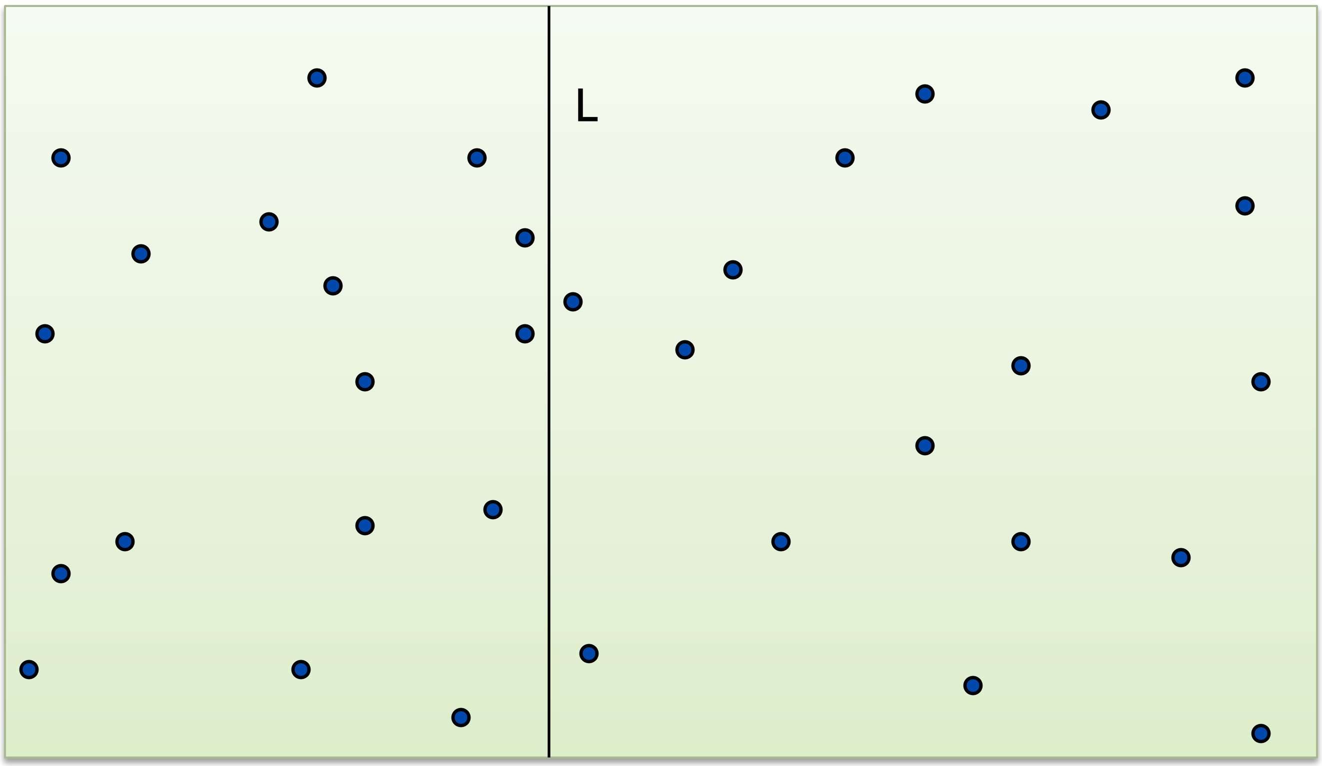
Divide. Sub-divide region into 4 quadrants.

Obstacle. Impossible to ensure n/4 points in each piece.



# Algorithm.

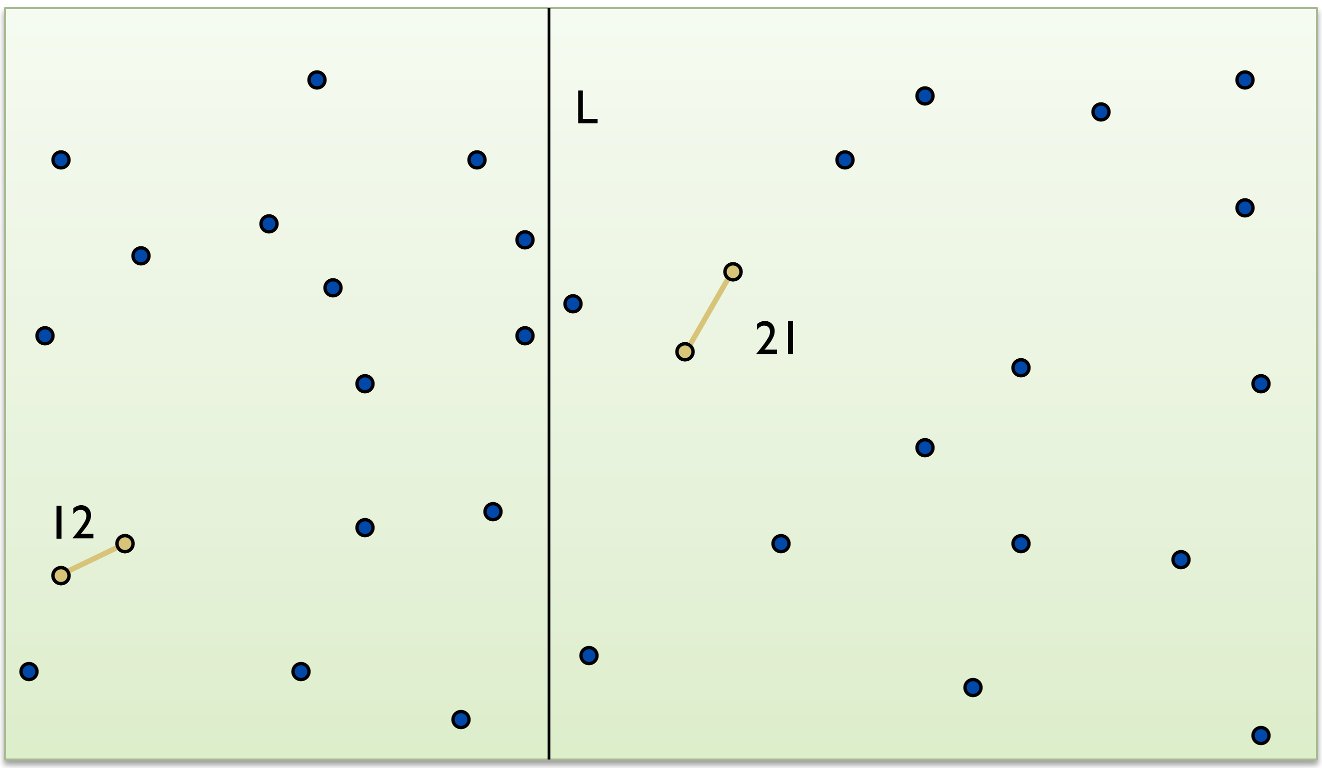
Divide: draw vertical line L with ≈ n/2 points on each side.



# Algorithm.

Divide: draw vertical line L with ≈ n/2 points on each side.

Conquer: find closest pair on each side, recursively.



# Algorithm.

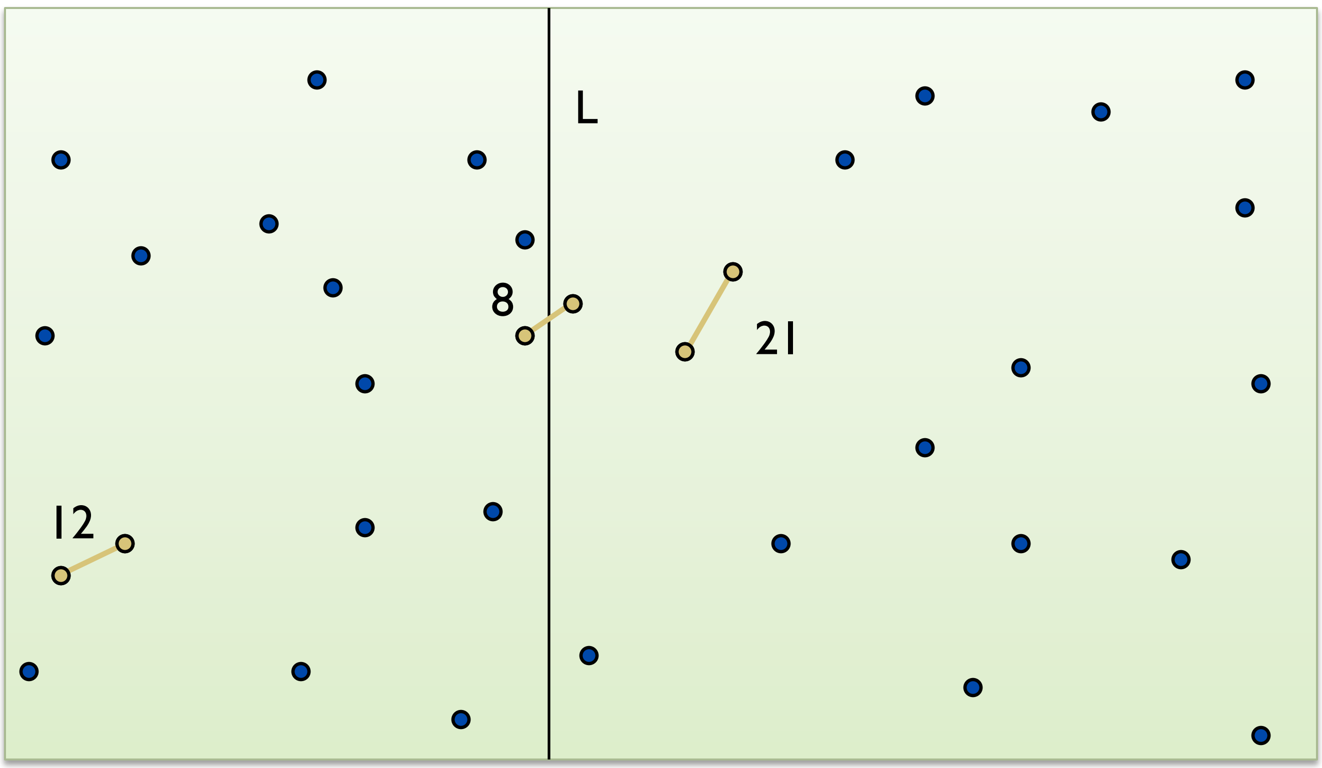
Divide: draw vertical line L with ≈ n/2 points on each side.

Conquer: find closest pair on each side, recursively.

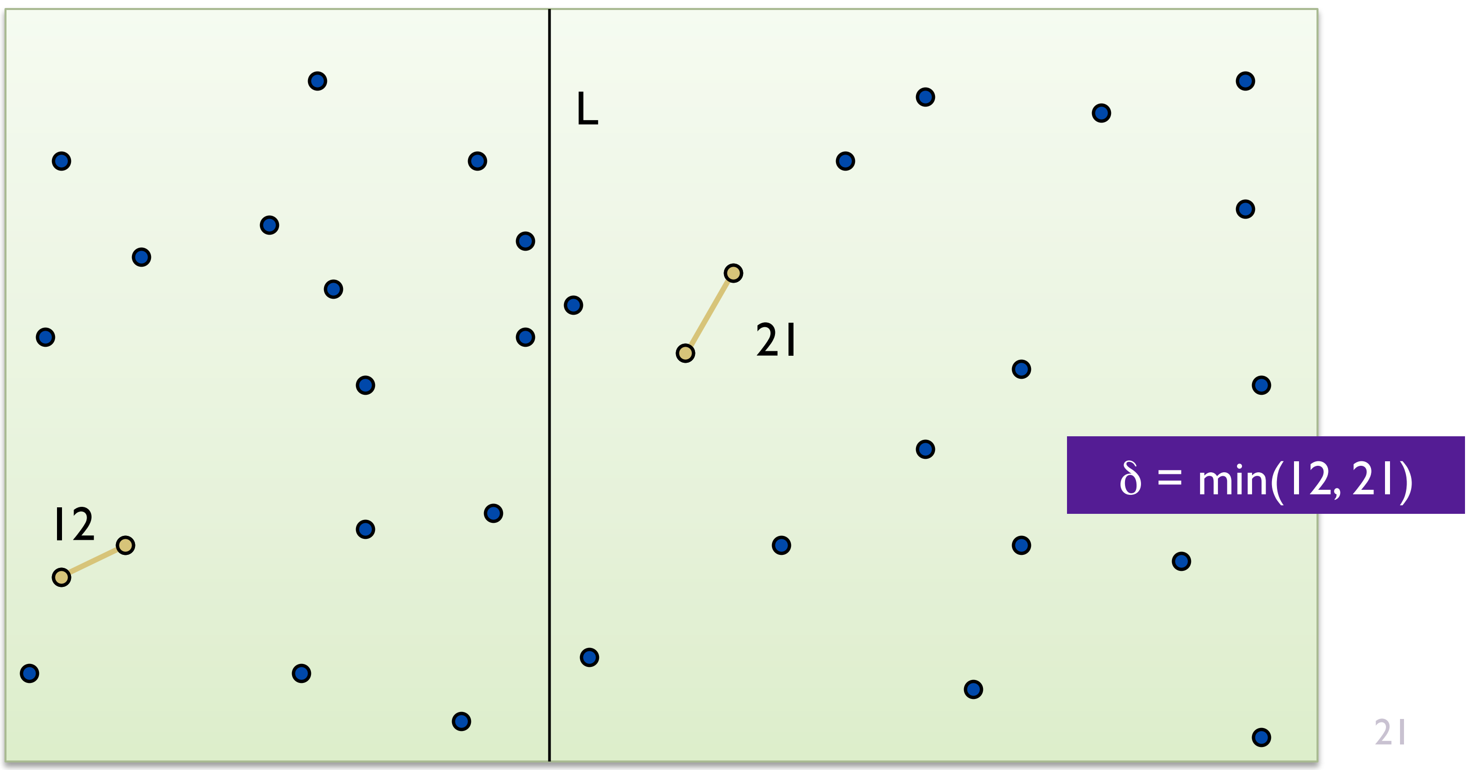
Combine: find closest pair with one point in each side.

seems like $\Theta(n^2)$ ?

Return best of 3 solutions.

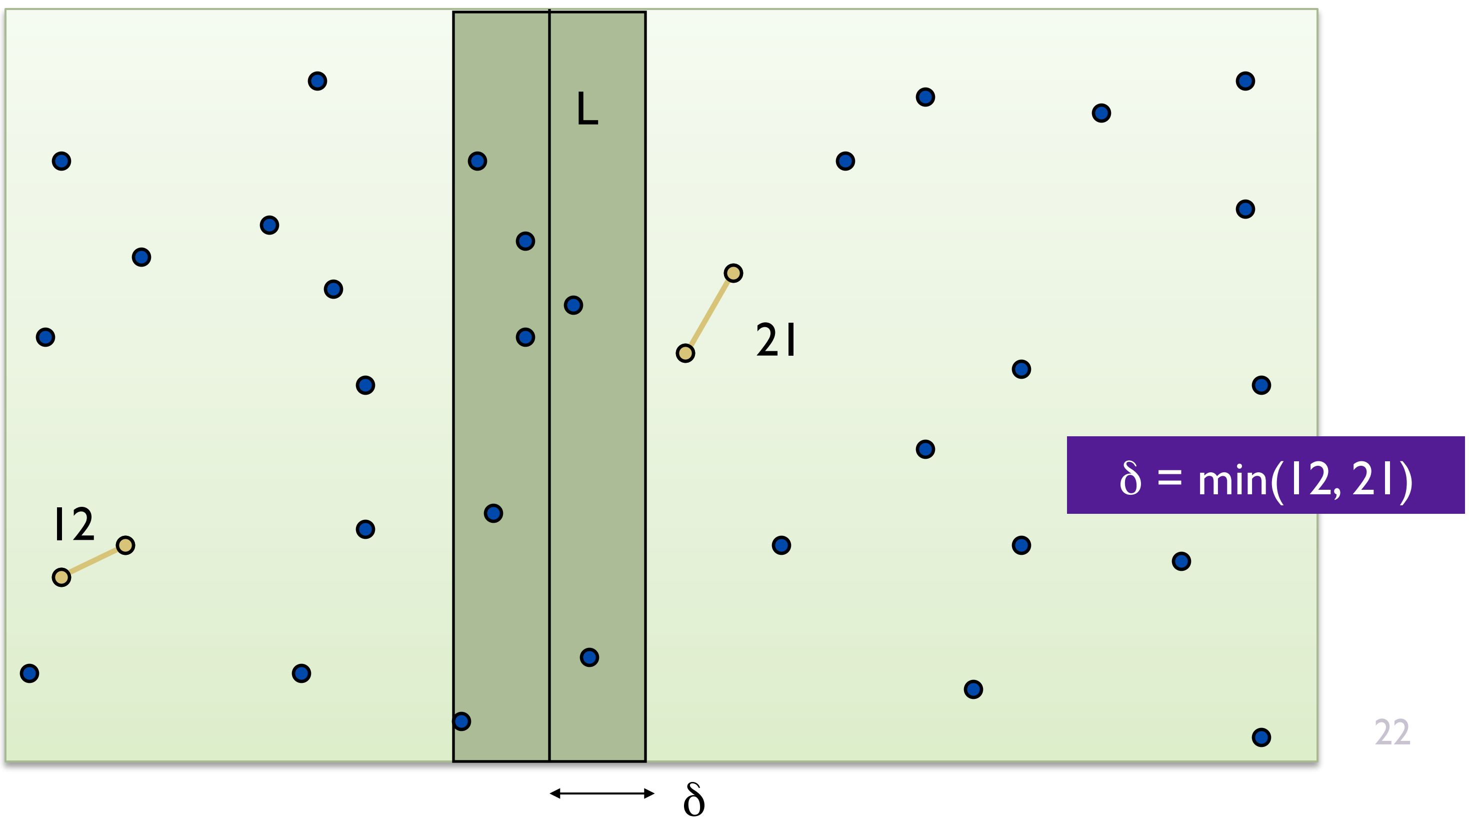


Find closest pair with one point in each side, *assuming* distance < δ.



# Find closest pair with one point in each side, *assuming* distance < δ.

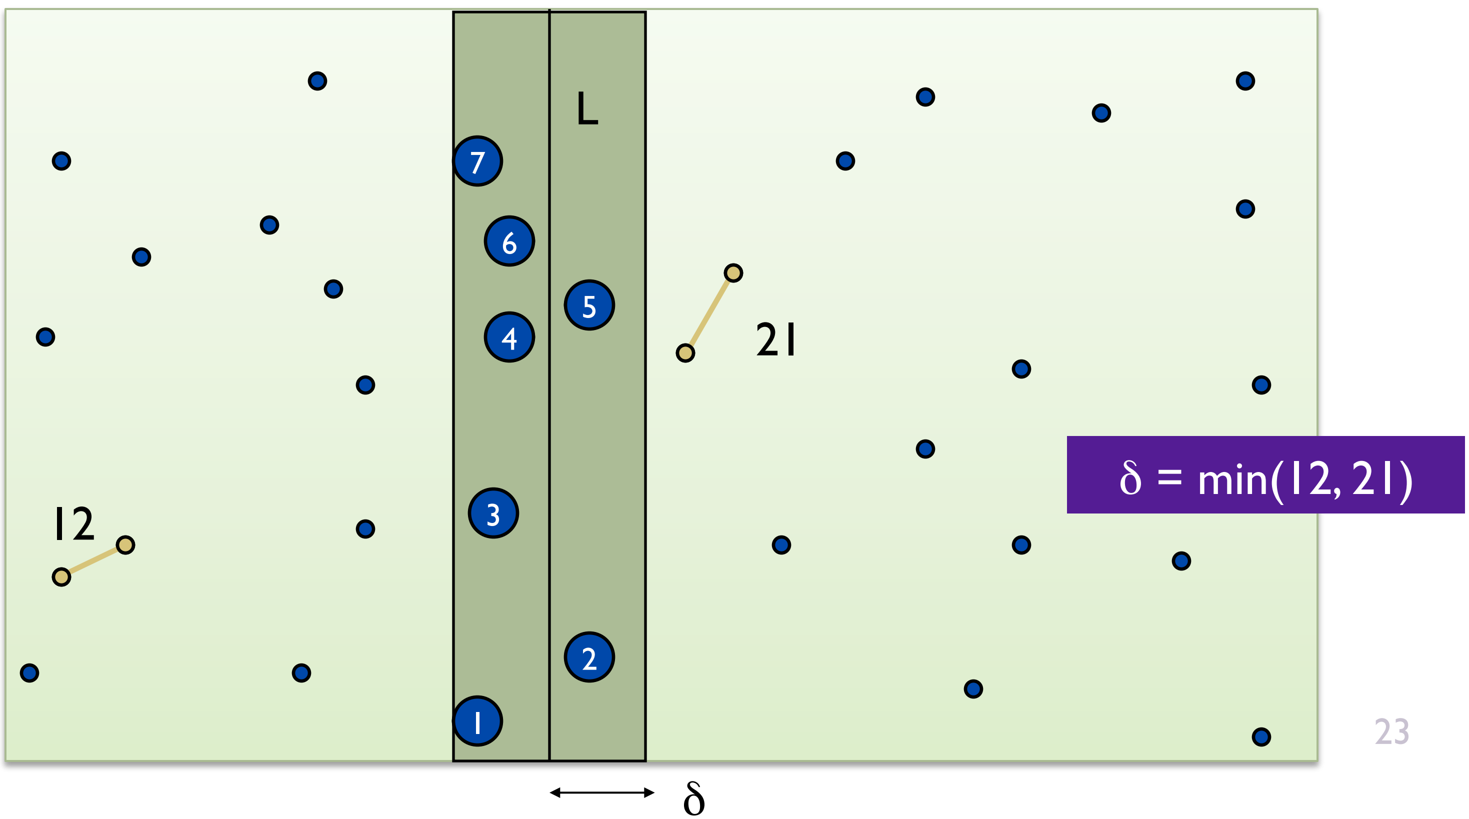
Observation: suffices to consider points within δ of line L.



# Find closest pair with one point in each side, *assuming* distance < δ.

Observation: suffices to consider points within δ of line L.

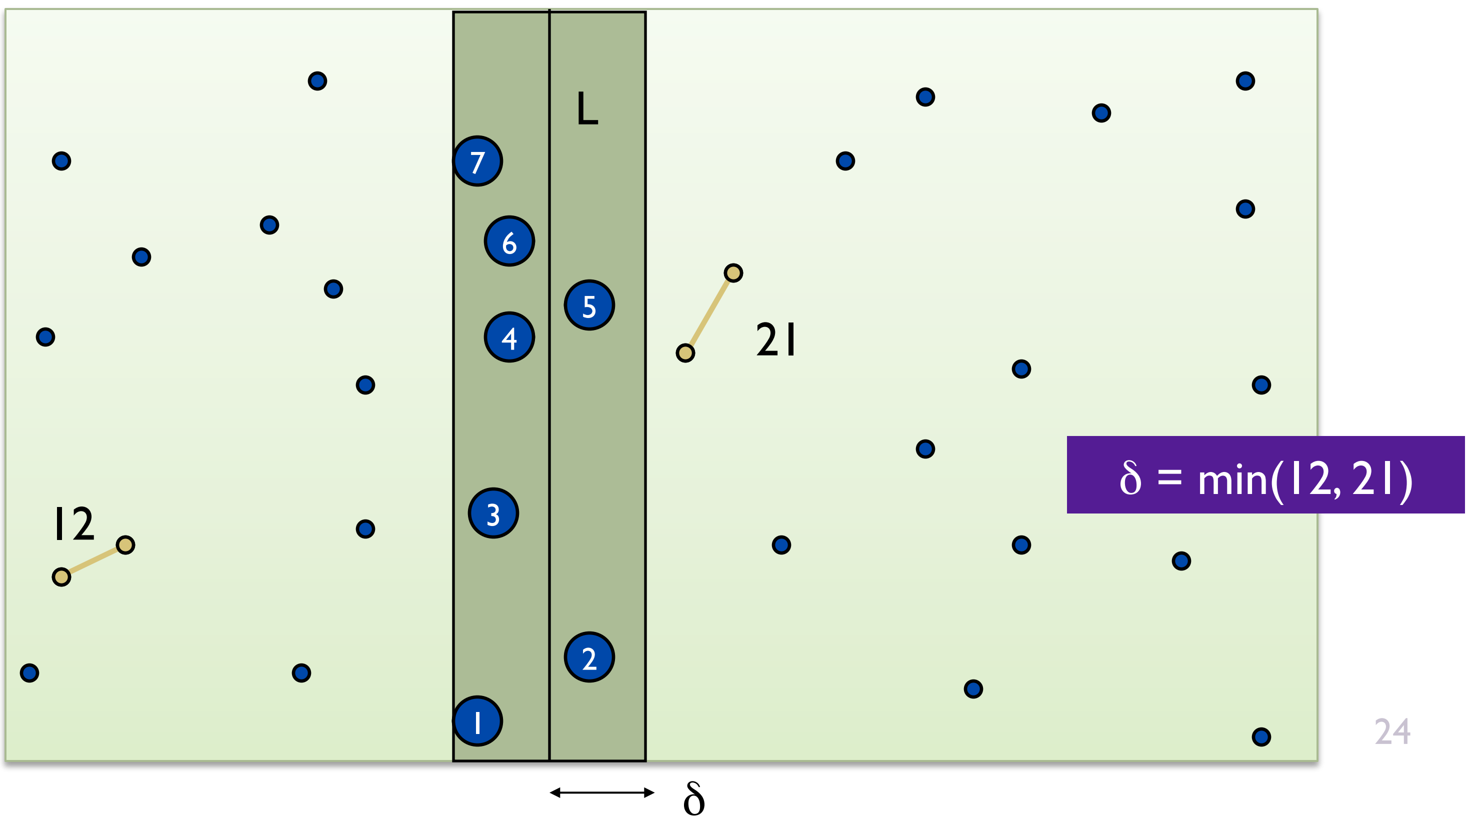
Almost the one-D problem again: Sort points in 2δ-strip by their y coordinate.



# Find closest pair with one point in each side, *assuming* distance < δ.

Observation: suffices to consider points within δ of line L.

Almost the one-D problem again: Sort points in 2δ-strip by their y coordinate. Only check pts within 8 in sorted list!



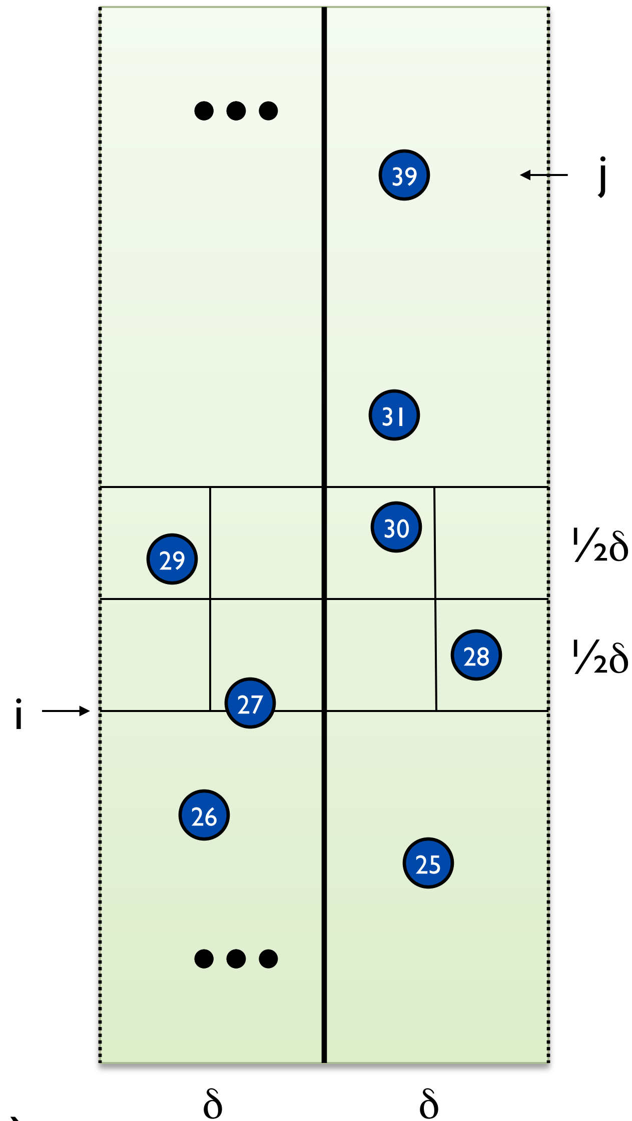
Def. Let $s_i$ have the $i^{th}$ smallest y-coordinate among points in the $2\delta$-width-strip.

Claim. If $|i - j| > 8$, then the distance between $s_i$ and $s_j$ is $> \delta$.

Pf: No two points lie in the same $\frac{1}{2}\delta$-by-$\frac{1}{2}\delta$ box:

$$\sqrt{\left(\frac{1}{2}\right)^2 + \left(\frac{1}{2}\right)^2} = \sqrt{\frac{1}{2}} = \frac{\sqrt{2}}{2} \approx 0.7 < 1$$

only 8 boxes within $+\delta$ of $y(s_i)$.



```
Closest-Pair(p₁, …, pₙ) {
   if(n <= ??) return ??

   Compute separation line L such that half the points
   are on one side and half on the other side.

   δ₁ = Closest-Pair(left half)
   δ₂ = Closest-Pair(right half)
   δ  = min(δ₁, δ₂)

   Delete all points further than δ from separation line L

   Sort remaining points p[1]…p[m] by y-coordinate.

   for i = 1..m
      k = 1
      while i+k <= m && p[i+k].y < p[i].y + δ
        δ = min(δ, distance between p[i] and p[i+k]);
        k++;

   return δ.
}
```

Analysis, I: Let D(n) be the number of pairwise distance calculations in the Closest-Pair Algorithm when run on n ≥ 1 points

$$D(n) \le \begin{cases} 0 & n = 1 \\ 2D(n/2) + 7n & n > 1 \end{cases} \Rightarrow D(n) = O(n \log n)$$

BUT – that's only the number of *distance calculations*

What if we counted comparisons?

Analysis, II: Let C(n) be the number of comparisons between coordinates/distances in the Closest-Pair Algorithm when run on $n \geq 1$ points

$$C(n) \leq \begin{cases} 0 & n = 1 \\ 2C(n/2) + O(n \log n) & n > 1 \end{cases} \Rightarrow C(n) = O(n \log^2 n)$$

Q. Can we achieve O(n log n)?

A. Yes. Don't sort points from scratch each time.

- Sort by x at top level only.
- Each recursive call returns δ *and* list of all points sorted by y
- Sort by merging two pre-sorted lists.

$$T(n) \leq 2T(n/2) + O(n) \Rightarrow \mathrm{T}(n) = O(n \log n)$$

## Going From Code to Recurrence

Carefully define what you're counting, and *write it down*!

"Let C(n) be the number of comparisons between sort keys used by MergeSort when sorting a list of length n ≥ 1"

In code, clearly separate *base case* from *recursive case,* highlight *recursive calls,* and *operations being counted.*

Write Recurrence(s)

Base Case

```
MS(A: array[1..n]) returns array[1..n] {
    If(n=1) return A;
    New L:array[1:n/2] = MS(A[1..n/2]);
    New R:array[1:n/2] = MS(A[n/2+1..n]);
    Return(Merge(L,R));
    }
Merge(A,B: array[1..n]) {
    New C: array[1..2n];
    a=1; b=1;
    For i = 1 to 2n {
        C[i] = "smaller of A[a], B[b] and a++ or b++";
    Return C;
    }
```

Recursive calls

One Recursive Level

Operations being counted

Base case

$$C(n) = \begin{cases} 0 & \text{if } n = 1 \\ 2C(n/2) + (n-1) & \text{if } n > 1 \end{cases}$$

Recursive calls

One compare per element added to merged list, except the last.

Total time: proportional to C(n)

(loops, copying data, parameter passing, etc.)

Carefully define what you're counting, and *write it down*!

> "Let D(n) be the number of pairwise distance calculations in the Closest-Pair Algorithm when run on n ≥ 1 points"

In code, clearly separate *base case* from *recursive case,* highlight *recursive calls,* and *operations being counted*.

Write Recurrence(s)

# closest pair algorithm

Basic operations: distance calcs

```
Closest-Pair(p₁, …, pₙ) {
   if(n <= 1) return ∞

   Compute separation line L such that half the points
   are on one side and half on the other side.

   δ₁ = Closest-Pair(left half)
   δ₂ = Closest-Pair(right half)
   δ  = min(δ₁, δ₂)

   Delete all points further than δ from separation line L

   Sort remaining points p[1]…p[m] by y-coordinate.

   for i = 1..m
      k = 1
      while i+k <= m && p[i+k].y < p[i].y + δ
        δ = min(δ, distance between p[i] and p[i+k]);
        k++;

   return δ.
}
```

Base Case

Recursive calls (2)

Basic operations at this recursive level

One recursive level

0

2D(n / 2)

O(n)

Analysis, I: Let D(n) be the number of pairwise distance calculations in the Closest-Pair Algorithm when run on n ≥ 1 points

$$D(n) \le \begin{cases} 0 & n = 1 \\ 2D(n/2) + 7n & n > 1 \end{cases} \Rightarrow D(n) = O(n \log n)$$

BUT – that's only the number of *distance calculations*

What if we counted comparisons?

Carefully define what you're counting, and *write it down*!

“Let D(n) be the number of comparisons between coordinates/distances in the Closest-Pair Algorithm when run on n ≥ 1 points”

In code, clearly separate *base case* from *recursive case,* highlight *recursive calls,* and *operations being counted*.

Write Recurrence(s)

# closest pair algorithm

Basic operations:
*comparisons*

```
Closest-Pair(p1, …, pn) {
   if(n <= 1) return ∞

   Compute separation line L such that half the points
   are on one side and half on the other side.

   δ1 = Closest-Pair(left half)
   δ2 = Closest-Pair(right half)
   δ  = min(δ1, δ2)

   Delete all points further than δ from separation line L

   Sort remaining points p[1]…p[m] by y-coordinate.

        δ = min(δ, distance between p[i] and p[i+k]);
        k++;

   return δ.
}
```

Base Case

Recursive calls (2)

Basic operations at this recursive level

One recursive level

0

O(n log n)

2C(n / 2)

1

O(n)

O(n log n)

O(n)

Analysis, II: Let C(n) be the number of comparisons of coordinates/distances in the Closest-Pair Algorithm when run on n ≥ 1 points

$$C(n) \le \begin{cases} 0 & n = 1 \\ 2C(n/2) + O(n \log n) & n > 1 \end{cases} \Rightarrow C(n) = O(n \log^2 n)$$

Q. Can we achieve time O(n log n)?

A. Yes. Don't sort points from scratch each time.

Sort by x at top level only.

Each recursive call returns δ *and* list of all points sorted by y

Sort by merging two pre-sorted lists.

$$T(n) \le 2T(n/2) + O(n) \Rightarrow \mathrm{T}(n) = O(n \log n)$$

# Integer Multiplication

Add. Given two n-bit integers a and b, compute a + b.

Add

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| 1 | 1 | 1 | 1 | 1 | 1 | 0 | 1 | |
| | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 |
| + | 0 | 1 | 1 | 1 | 1 | 1 | 0 | 1 |
| 1 | 0 | 1 | 0 | 1 | 0 | 0 | 1 | 0 |

O(n) bit operations.

Add. Given two n-bit integers a and b, compute a + b.

Add

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| 1 | 1 | 1 | 1 | 1 | 1 | 0 | 1 | |
| | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 |
| + | 0 | 1 | 1 | 1 | 1 | 1 | 0 | 1 |
| 1 | 0 | 1 | 0 | 1 | 0 | 0 | 1 | 0 |

O(n) bit operations.

Multiply. Given two n-bit integers a and b, compute a × b.
The "grade school" method:

Multiply

| | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 |
| | | | | | | | * | 0 | 1 | 1 | 1 | 1 | 1 | 0 | 1 |
| | | | | | | | | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 |
| | | | | | | | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | |
| | | | | | | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | | |
| | | | | | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | | | |
| | | | | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | | | | |
| | | | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | | | | | |
| | | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | | | | | | |
| | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | | | | | | | |
| 0 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

$\Theta(n^2)$ bit operations.

# divide & conquer multiplication: warmup

## To multiply two 2-digit integers:

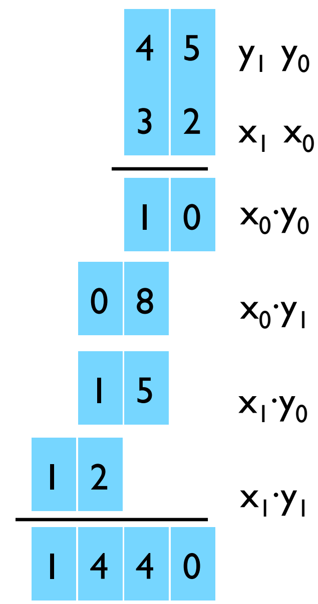
Multiply four 1-digit integers.

Add, shift some 2-digit integers to obtain result.

$$
\begin{aligned}
x &= 10\cdot x_1 + x_0 \\
y &= 10\cdot y_1 + y_0 \\
xy &= \left(10\cdot x_1 + x_0\right)\left(10\cdot y_1 + y_0\right) \\
&= 100\cdot x_1 y_1 + 10\cdot\left(x_1 y_0 + x_0 y_1\right) + x_0 y_0
\end{aligned}
$$

Same idea works for *long* integers –

can split them into 4 half-sized ints



# divide & conquer multiplication: warmup

## To multiply two n-bit integers:

Multiply four ½n-bit integers.

Add two ½n-bit integers, and shift to obtain result.

$$
\begin{aligned}
x &= 2^{n/2} \cdot x_1 + x_0 \\
y &= 2^{n/2} \cdot y_1 + y_0 \\
xy &= \left(2^{n/2} \cdot x_1 + x_0\right)\left(2^{n/2} \cdot y_1 + y_0\right) \\
&= 2^n \cdot x_1 y_1 + 2^{n/2} \cdot \left(x_1 y_0 + x_0 y_1\right) + x_0 y_0
\end{aligned}
$$

| | | | | |
|---|---|---|---|---|
| | | 1 1 0 1 | 0 1 0 1 | $y_1$ $y_0$ |
| | | * 0 1 1 1 | 1 1 0 1 | $x_1$ $x_0$ |
| | | 0 1 0 0 | 0 0 0 1 | $x_0 \cdot y_0$ |
| | 1 0 1 0 | 1 0 0 1 | | $x_0 \cdot y_1$ |
| | 0 0 1 0 | 0 0 1 1 | | $x_1 \cdot y_0$ |
| 0 1 0 1 | 1 0 1 1 | | | $x_1 \cdot y_1$ |
| 0 1 1 0 | 1 0 0 0 | 0 0 0 0 | 0 0 0 1 | |

$$
\mathrm{T}(n) = \underbrace{4T(n/2)}_{\text{recursive calls}} + \underbrace{\Theta(n)}_{\text{add, shift}} \Rightarrow \mathrm{T}(n) = \Theta(n^2)
$$

↑

assumes n is a power of 2

# key trick: 2 multiplies for the price of 1:

$$
\begin{aligned}
x &= 2^{n/2} \cdot x_1 + x_0 \\
y &= 2^{n/2} \cdot y_1 + y_0 \\
xy &= \left(2^{n/2} \cdot x_1 + x_0\right)\left(2^{n/2} \cdot y_1 + y_0\right) \\
&= 2^{n} \cdot x_1 y_1 + 2^{n/2} \cdot \left(x_1 y_0 + x_0 y_1\right) + x_0 y_0
\end{aligned}
$$

Well, ok, 4 for 3 is more accurate…

$$
\begin{aligned}
\alpha &= x_1 + x_0 \\
\beta &= y_1 + y_0 \\
\alpha\beta &= \left(x_1 + x_0\right)\left(y_1 + y_0\right) \\
&= x_1 y_1 + \left(x_1 y_0 + x_0 y_1\right) + x_0 y_0 \\
\left(x_1 y_0 + x_0 y_1\right) &= \alpha\beta - x_1 y_1 - x_0 y_0
\end{aligned}
$$

To multiply two n-bit integers:

- Add two ½n bit integers.
- Multiply three ½n-bit integers.
- Add, subtract, and shift ½n-bit integers to obtain result.

$$
\begin{aligned}
x &= 2^{n/2} \cdot x_1 + x_0 \\
y &= 2^{n/2} \cdot y_1 + y_0 \\
xy &= 2^{n} \cdot x_1 y_1 + 2^{n/2} \cdot \left(x_1 y_0 + x_0 y_1\right) + x_0 y_0 \\
&= 2^{n} \cdot \underset{\text{A}}{x_1 y_1} + 2^{n/2} \cdot \left( \underset{\text{B}}{(x_1 + x_0)(y_1 + y_0)} - \underset{\text{A}}{x_1 y_1} - \underset{\text{C}}{x_0 y_0} \right) + \underset{\text{C}}{x_0 y_0}
\end{aligned}
$$

Theorem. [Karatsuba-Ofman, 1962] Can multiply two n-digit integers in $O(n^{1.585})$ bit operations.

$$
\mathrm{T}(n) \le \underbrace{T\left(\lfloor n/2 \rfloor\right) + T\left(\lceil n/2 \rceil\right) + T\left(1 + \lceil n/2 \rceil\right)}_{\text{recursive calls}} + \underbrace{\Theta(n)}_{\text{add, subtract, shift}}
$$

$$
\textit{Sloppy version}: \; T(n) \le 3T(n/2) + O(n)
$$

$$
\Rightarrow \mathrm{T}(n) = O(n^{\log_2 3}) = O(n^{1.585})
$$

Naïve: $\Theta(n^2)$

Karatsuba: $\Theta(n^{1.59\ldots})$

Amusing exercise: generalize Karatsuba to do 5 size n/3 subproblems $\rightarrow \Theta(n^{1.46\ldots})$

Best known: $\Theta(n \log n \log\log n)$

"Fast Fourier Transform"

but mostly unused in practice (unless you need really big numbers - a billion digits of $\pi$, say)

High precision arithmetic *IS* important for crypto

Idea:

“Two halves are better than a whole”

if the base algorithm has super-linear complexity.

“If a little's good, then more's better”

repeat above, recursively

Applications: Many.

Binary Search, Merge Sort, (Quicksort), Closest points, Integer multiply,…

## Recurrences

Above: Where they come from, how to find them

Next: how to solve them

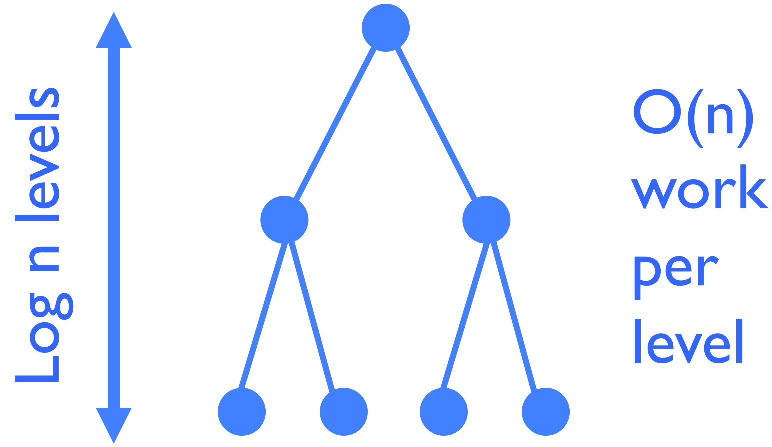
Mergesort: (recursively) sort 2 half-lists, then merge results.

$T(n) = 2T(n/2)+cn, \quad n \geq 2$

$T(1) = 0$

Solution: $\Theta(n \log n)$
(~~details~~ later)

now



Solve: $T(1) = c$

$T(n) = 2\,T(n/2) + cn$

| $k$ | $3^k$ | $n/2^k = 1$ | $3^k\,T(1)$ |

$n = 2^k$ ; $k = \log_2 n$

Total Work: $T(n) = \sum_{i=0}^{k} 3^i cn / 2^i$

Theorem:

$$1 + x + x^2 + x^3 + \ldots + x^k = (x^{k+1}-1)/(x-1)$$

proof:

$$\begin{aligned} y &= 1 + x + x^2 + x^3 + \ldots + x^k \\ xy &= \phantom{1 +{}} x + x^2 + x^3 + \ldots + x^k + x^{k+1} \\ xy-y &= x^{k+1} - 1 \\ y(x-1) &= x^{k+1} - 1 \\ y &= (x^{k+1}-1)/(x-1) \end{aligned}$$

## Solve: $T(1) = c$
## $T(n) = 3\,T(n/2) + cn$ (cont.)

$$T(n) = \sum_{i=0}^{k} 3^i cn / 2^i$$

$$= cn \sum_{i=0}^{k} 3^i / 2^i$$

$$= cn \sum_{i=0}^{k} \left(\tfrac{3}{2}\right)^i$$

$$= cn \frac{\left(\tfrac{3}{2}\right)^{k+1} - 1}{\left(\tfrac{3}{2}\right) - 1}$$

$$\sum_{i=0}^{k} x^i = \frac{x^{k+1} - 1}{x - 1} \quad (x \neq 1)$$

Solve: $T(1) = c$

$T(n) = 3\,T(n/2) + cn$ (cont.)

$$cn\frac{\left(\frac{3}{2}\right)^{k+1}-1}{\left(\frac{3}{2}\right)-1} = 2cn\left(\left(\frac{3}{2}\right)^{k+1}-1\right)$$

$$< 2cn\left(\frac{3}{2}\right)^{k+1}$$

$$= 3cn\left(\frac{3}{2}\right)^{k}$$

$$= 3cn\frac{3^k}{2^k}$$

Solve: $T(1) = c$

$T(n) = 3\,T(n/2) + cn$ (cont.)

$$3cn\frac{3^k}{2^k} = 3cn\frac{3^{\log_2 n}}{2^{\log_2 n}}$$

$$= 3cn\frac{3^{\log_2 n}}{n}$$

$$= 3c3^{\log_2 n}$$

$$= 3c\left(n^{\log_2 3}\right)$$

$$\boxed{= O\left(n^{1.59\ldots}\right)}$$

$$a^{\log_b n}$$

$$= \left(b^{\log_b a}\right)^{\log_b n}$$

$$= \left(b^{\log_b n}\right)^{\log_b a}$$

$$= n^{\log_b a}$$

$T(n) = aT(n/b)+cn^k$ for $n > b$ then

$a > b^k \Rightarrow T(n) = \Theta(n^{\log_b a})$ [many subprobs → leaves dominate]

$a < b^k \Rightarrow T(n) = \Theta(n^k)$ [few subprobs → top level dominates]

$a = b^k \Rightarrow T(n) = \Theta(n^k \log n)$ [balanced → all log n levels contribute]

Fine print:

$a \geq 1$; $b > 1$; $c, d, k \geq 0$; $T(1) = d$; $n = b^t$ for some $t > 0$;
a, b, k, t integers. True even if it is $\lceil n/b \rceil$ instead of $n/b$.

Expanding recurrence as in earlier examples, to get

$T(n) = n^g ( d + c S )$

where $g = \log_b(a)$ and $S = \sum_{j=1}^{\log_b n} x^j$, where $x = b^k/a$.

If c = 0 the sum S is irrelevant, and $T(n) = O(n^g)$: all the work happens in the base cases, of which there are $n^g$, one for each leaf in the recursion tree.

If c > 0, then the sum matters, and splits into 3 cases (like previous slide):

- if $x < 1$, then $S < x/(1-x) = O(1)$. [S is just the first log n terms of the infinite series with that sum].
- if $x = 1$, then $S = \log_b(n) = O(\log n)$. [all terms in the sum are 1 and there are that many terms].
- if $x > 1$, then $S = x * (x^{1+\log_b(n)}-1)/(x-1)$. After some algebra, $n^g * S = O(n^k)$

Power(a,n)

**Input:** integer $n$ and number $a$

**Output:** $a^n$

Obvious algorithm

$n-1$ multiplications

Observation:

if $n$ is even, $n = 2m$, then $a^n = a^m \cdot a^m$

```
Power(a,n)
   if n = 0 then return(1)
   if n = 1 then return(a)
   x ← Power(a,⌊n/2⌋)
   x ← x•x
   if n is odd then
        x ← a•x
   return(x)
```

Let M(n) be number of multiplies

Worst-case recurrence:

$$M(n) = \begin{cases} 0 & n \le 1 \\ M\left(\lfloor n/2 \rfloor\right) + 2 & n > 1 \end{cases}$$

By master theorem

$M(n) = O(\log n)$ (a=1, b=2, k=0)

More precise analysis:

$M(n) = \lfloor \log_2 n \rfloor$ + (# of 1's in n's binary representation) - 1

Time is O(M(n)) if numbers < word size, else also depends on length, multiply algorithm

Instead of $a^n$ want $a^n$ mod $N$

$a^{i+j}$ mod $N$ = (($a^i$ mod $N$) • ($a^j$ mod $N$)) mod $N$

same algorithm applies with each $x \cdot y$ replaced by

(($x$ mod $N$) • ($y$ mod $N$)) mod $N$

In RSA cryptosystem (widely used for security)

need $a^n$ mod $N$ where $a$, $n$, $N$ each typically have 1024 bits

Power: at most 2048 multiplies of 1024 bit numbers

relatively easy for modern machines

Naive algorithm: $2^{1024}$ multiplies

Idea:

- "Two halves are better than a whole"
  - if the base algorithm has super-linear complexity.
- "If a little's good, then more's better"
  - repeat above, recursively

Analysis: recursion tree or Master Recurrence

Applications: Many.

- Binary Search, Merge Sort, (Quicksort), Closest points, Integer multiply, exponentiation,…
